

Chapter 24 - Executable Knowledge: Stage 7 of Semantic Knowledge Development Lifecycle

From Intelligent Knowledge to Actionable Systems

The first six stages of the Semantic Knowledge Development Lifecycle (SKDL) transformed an abstract conceptual vocabulary into a **validated, intelligent, machine-reasonable** knowledge asset.

- Conceptual Modeling gave us structure.
- Semantic Description gave us meaning.
- Knowledge Reuse gave us composability.
- Semantic Governance gave us discipline.
- Semantic Validation gave us trust.
- Semantic Reasoning gave us intelligence.

Now, as knowledge begins to flow from ontology models into **production systems**, a new challenge emerges:

"How do we act on this knowledge?"

Executable Knowledge answers this question.

It is the discipline of encoding semantic knowledge with sufficient logical constraints to be interpreted deterministically and to drive action -- closing the loop between reasoning and execution.

Executable Knowledge transforms an ontology from a system that *knows* into a system that *acts*.

This chapter examines Exercise 22 through 26 from Michael DeBellis' *Protégé 5 New OWL Pizza Tutorial* through the **lens of executability**. While **Exercise 20** and **Exercise 21 (Chapter (23))** demonstrated the power of reasoning. **Exercise 22-26** introduce the OWL constructs that make reasoning *actionable*: universal restrictions, closure axioms, enumerated classes, `hasValue` restriction, and cardinality restrictions.

These constructs are the **execution primitives** of an ontology. They are what separate a descriptive model from an operational one.

Along the way, we will examine executability from multiple complementary perspectives: mathematical, engineering, architectural, and industrial -- revealing that executable knowledge is not a new invention, but

the natural culmination of the entire SKDL arc.

24.1 Chapter Introduction -- From Intelligence to Action

24.1.1 The Journey So Far

The first six stages of the Semantic Knowledge Development Lifecycle established the foundations of ontology engineering.

Stage 1 -- Conceptual Modeling identified the concepts that define a knowledge domain and organized them into a coherent semantic taxonomy.

Stage 2 -- Semantic Description enriched those concepts with formal meaning using Description Logic, OWL restrictions, and class expressions.

Stage 3 -- Knowledge Reuse transformed validated semantic knowledge into reusable assets that could be shared, extended, and specialized systematically.

Stage 4 -- Semantic Governance established the policies, standards, and processes required to maintain semantic integrity across an evolving knowledge ecosystem.

Stage 5 -- Semantic Validation verified that the ontology is logically consistent, semantically complete, and fit for purpose before deployment.

Stage 6 -- Semantic Reasoning derived new knowledge through automated inference -- computing the logical consequences of the asserted axioms.

By the end of **Stage 6**, the `Pizza` ontology had become intelligent. The reasoner auto-classified `MargheritaPizza` and other cheese-topped pizzas as subclasses of `cheesyPizza`. The inferred hierarchy now contained knowledge that was never explicitly asserted.

The ontology had become **intelligent**.

But intelligent is **not action**.

An intelligent ontology that cannot act is like a brilliant advisor who never speaks. It contains valuable knowledge, but it does not use that knowledge to change the world.

It is passive, not active!

This is where **Stage 7 -- Executable Knowledge** enters the lifecycle.

24.1.2 The New Question

Reasoning asked: ***What else can this model tell us?***

Executable Knowledge asks: ***What should happen, given what we know?***

The distinction is fundamental.

Reasoning derives new knowledge from a validated ontology. Executable Knowledge uses that derived knowledge to **drive action**.

Without reasoning, execution has no foundation.

Without execution, reasoning has no consequence.

Together, they produce actionable intelligence.

24.1.3 The Central Insight

The central insight of this chapter is deceptively simple:

Every OWL axiom you write is a potential execution rule. The question is not whether your ontology can be executed -- it is whether you have written the axioms that make execution possible.

The reasoner infers facts.

But inference alone does not trigger action.

Action requires:

- **Determinism** -- the ontology must produce a single, unambiguous result
- **Completeness** -- the ontology must guarantee that required data is present
- **Closure** -- the ontology must define boundaries, not leave them open

These are not automatic. They must be **engineered** through deliberate axioms.

Exercise 22-26 introduce these axioms.

24.2 Learning Objectives

After completing this chapter, you should be able to achieve the following learning outcomes:

Knowledge:

- Explain why Executable Knowledge is the seventh stage of the Semantic Knowledge Development Lifecycle (SKDL)
- Distinguish between descriptive knowledge and executable knowledge
- Understand the role of universal restrictions, closure axioms, enumerated classes, `hasValue` restrictions, and cardinality restrictions in enabling execution
- Explain how the Open World Assumption affects executability
- Understand how OWL constructs become execution primitives in the EKA framework

Practical Skills:

- Create universal restrictions (`only`) in Protégé
- Define closure axioms using combinations of `only` and cardinality restrictions
- Create enumerated classes using `EquivalentTo`
- Define `hasValue` restrictions to bind properties to specific individuals
- Define cardinality restrictions (`min` , `max` , `exactly`) to enforce data completeness
- Test executability by running the reasoner against test individuals

Mathematical Perspective:

- Understand how closure axioms convert open-world semantics to closed-world specifications
- Explain the mathematical relationships between `some` , `only` , `exactly` , and `value` restrictions
- Understand how enumeration defines a finite value domain
- Explain how cardinality restrictions constrain the extension of a class

Historical Perspective:

- Trace the concept of executability from early expert systems to modern rule engines
- Understand how the "knowledge is action" principle connects to cybernetics, control theory, and business process management

Engineering Perspective:

- Understand execution as the operationalization of semantic knowledge
- Explain why closure axioms are necessary for deterministic execution
- Map executable knowledge to the Θ (Trigger) and Φ (Execution) layers in the EKA framework
- Apply executable knowledge to industrial scenarios (manufacturing, compliance, safety)

24.3 Positioning Within SKDL -- Stage 7 Highlighted

As introduced in **Chapter (17)**, ontology engineering progresses through seven stages of the Semantic Knowledge Development Lifecycle (SKDL), each stage contributing a distinct engineering objective toward the construction of **executable semantic knowledge systems**.

Having completed **Stage 6 -- Semantic Reasoning** in the previous chapter, this chapter advances to **Stage 7 -- Executable Knowledge**.

The objective of this stage is to operationalize semantic knowledge -- to encode the ontology with the constraints required for **deterministic, actionable** execution.

At the completion of **Stage 6**, the `Pizza` ontology contained an inferred hierarchy that included knowledge derived by the reasoner. However, the ontology was still **descriptive**. It could tell us that `MargheritaPizza` is a subclass of `cheesyPizza`. But it could not yet tell us what to **do** about it.
